

BALANCE YOUR LIFE IN MICROGRAVITY

Teacher: Murray Perl Scientist: Dr. Stephen Moore

Standards: A, C, E, F, G

Materials: Lesson plan and visual presentation Time: One class period

Preparation: Read lesson plan; Review slides

Motivation:

Strategy / Activity

Question / Issue

Anticipated Response / Understanding

1

Ask the class if anyone wants \$20. When a volunteer comes forward, stipulate that you will drop a twenty-dollar bill and they must catch it. Further

Students should describe the path from the eyes to the brain to the spinal chord to the muscles in the hand. This should explain why it takes so long for the student to attempt to catch the bill. This will later be contrasted with the speed of reflex. NB: If a student anticipates the drop, they can catch the bill! To prevent this possibility, ask the subject, "Are you ready?" and drop the bill before they respond. This will break the subject's concentration and prevent him/her from anticipating the moment you drop the bill.

stipulate that the bill must be caught between the thumb and forefinger and their hand must be stationary. After dropping the bill several times students realize it cannot be caught. **Ask the class to trace the neural pathway involved in catching the bill.**

Development: How are nerve impulses transmitted?

2

Show NEURON

Ask students how a nerve impulse is transmitted along a neuron.

Nerve impulses are transmitted as a depolarization along the neuron. (Depolarization takes place when Calcium (Ca+) and sodium (Na+) ions enter the cell. If this process is sufficient, an action potential is stimulated, causing potassium (K+) to leave the cell to repolarize the membrane. This depolarization-repolarization continues along the axon until it reaches the presynaptic terminal, where a neurotransmitter is released to communicate the signal to the next neuron.)

Ask students to describe the synapse.

It is a gap between the terminal branches of a neuron and the dendrites of the next neuron.

Ask students how the nerve message crosses the synapse.

The synaptic vesicle secretes a neurotransmitter across the synaptic cleft. The neurotransmitter fits into a receptor that triggers a depolarization in the next neuron.

3

Show SYNAPSE

Compare the speed of conduction along the neuron to the speed across the synapse.

The conduction speed of the electrical depolarization is relatively rapid along the neuron. The speed of the neural message must slow down drastically as the neurotransmitter is secreted across the synapse.

Strategy / Activity	Question / Issue	Anticipated Response / Understanding
<p>4</p> <p>Blast an air horn (Or create another loud noise, i.e. drop a textbook on a flat surface; clap your hands loudly, whistle) near an unsuspecting student.</p>  <p>Show REFLEX ARC</p>	<p>Note his/her response to the loud noise.</p> <p>Ask students to compare the neural pathway in a reflex to the voluntary pathway described earlier. Explain why the reflex response is so much more rapid than a voluntary response.</p>	<p>Students should note that the response was nearly instantaneous.</p> <p>The reflex does not involve transmission to the brain and requires transmission across fewer synapses. A reflex bypasses the brain. Transmission across a synapse is much slower than conduction along the neuron.</p>

How do we keep ourselves upright?

<p>5</p>  <p>Ask students to stand on one leg</p>	<p>Ask students to note the activity of their body as they attempt to maintain their balance.</p>	<p>The muscles in the legs are contracting and relaxing to maintain equilibrium.</p> <p><u>Proprioception</u>: the process by which the body can vary muscle contraction in immediate response to incoming information regarding external forces -</p> <p><i>The Role of Muscle Spindles in Posture and Movement.</i> http://www.umds.ac.uk/physiology/mcal/posture.html</p>
<p>6</p>  <p>Show PROPRIOCEPTOR</p>	<p>Explain that proprioceptors in their muscles and joints are sensing body position and relaying this information to the brain.</p>	<p>The proprioceptors and the muscles interact to adjust muscle tension to maintain balance.</p>

How do we detect rotational motion?

Strategy / Activity	Question / Issue	Anticipated Response / Understanding
<p>1 5</p> 	<p>What is rotational motion?</p>	<p>The motion of an object around an axis in a circular path.</p>
<p>1 6</p>  <p>Show SEMI - CIRCULAR CANALS</p>	<p>Have students describe their structure. Describe the various ways the head can move. Ask why they would be oriented in three planes 90° apart.</p>	<p>The semicircular canals are oriented in three planes 90° apart to respond to motion in each plane (pitch, yaw, and roll). Using the shuttle as an example, here is a graphical example:</p>  <p>http://liftoff.msfc.nasa.gov/academy/rocket_sci/shuttle/attitude/pyr.html</p>
<p>1 7</p>  <p>Show CUPULA</p>	<p>Point out the architectural origin of the word.</p>	<p>Cupula is derived from the domed architectural feature on cathedrals.</p>
<p>1 8</p>  <p>Show CUPULA AT REST</p>	<p>Have students describe the structure of the cupula. Compare the structure of the cupula in the semicircular canals to the otolith organs</p>	<p>The cupula is a gelatinous structure like the gel in the otolith organs. It does not have otoliths on top because it does not respond to gravity, but to movement of the head.</p>

Strategy / Activity	Question / Issue	Anticipated Response / Understanding
<p>19</p>  <p>Show THE EFFECT OF ROTATION ON THE CUPULA</p> <p>Application of scientific principles.</p>	<p>Describe what happens to the cupula as the dancer spins.</p> <p>Why does the room appear to continue to spin even after the dancer stops?</p>	<p>The movement of the fluid (endolymph) in the semicircular canal bends the cupula and the attached hairs triggering depolarization.</p> <p>The fluid (endolymph) continues to circulate for a short time after the bodies motion stops.</p>

What is the role of the eyes in maintaining balance?

<p>Have students pairs face each other, one takes the role of observer and the other is experimental subject. The subject will move his/her head from side to side while focused on the nose of the observer. The observer will note the movement of the subject's eyes. Reverse the roles and observe the eye movement.</p> <p>20</p>  <p>Show VESTIBULO-OCULAR REFLEX</p>	<p>Ask students to describe the relationship between the head movement and the eye movement.</p> <p>Ask students to describe the Vestibulo-ocular reflex. Why is this reflex? What is the function of this reflex?</p>	<p>The eyes move opposite to the movement of the head. The degree of movement is identical for the head and eyes.</p> <p>The eyes move exactly opposite to the movement of the head because there is a reflex connecting the cupula to the visual cortex in the brain. This allows us to maintain focus on an object even while the head is moving. Without this reflex we would see the world bobbing up and down as we walked. (Imagine viewing the world as seen in the movie "The Blair Witch Project".)</p>

How does the brain integrate sensory input to maintain balance?

Strategy / Activity	Question / Issue	Anticipated Response / Understanding
---------------------	------------------	--------------------------------------

Medial summary

Have students recall the four major sources of sensory input used to maintain balance.

Muscles, eyes, otoliths, cupula in semicircular canals.

Ask student how they maintained their balance when standing on one foot.

Sensory input from muscles, eyes, otoliths, and cupula in semicircular canals causes the brain to respond by adjusting muscle tension to regain homeostasis.

Show FEEDBACK SYSTEM

Ask the class, which of the four sensory input modes depend on gravity? (Eyes)(Muscles)(Otoliths)(Semicircular canals) Why?

The otoliths and proprioceptors in the muscles depend on gravity to function. Review which components of the vestibular system are functioning in microgravity and which are not.

Show WHICH SENSORY INPUTS OPERATE IN MICROGRAVITY?

Ask students how astronauts know which way is up in microgravity.

Visual cues are the only method of orientation that operates in space.

Show HOW DO WE KNOW WHICH WAY IS UP IN SPACE?
